

MINDSTONE LYON AI MEETUP — 22 SEPTEMBER 2026 — EPITECH LYON

What I Learned Building With LLMs

A bug-fixing AI agent that lets non-technical
people contribute to code — without writing code

David Aparicio

Senior DevSecOps · Eudonet · INSA de Lyon / Unicamp (Brazil)

1st place — Dust/Qonto AI Agent Hackathon 2025

@dadideo

The problem we all know

Today

Marketing finds a typo on the website

- Files a ticket
- Waits for the sprint
- Developer picks it up
- Days or weeks later...

A 30-second fix takes 30 days

With the agent

Marketing describes the problem in plain language

- AI reads the code
- AI writes the fix
- Opens a pull request
- Developer reviews

Minutes, not weeks

How it works

Think of it like a spell-checker for your entire app — you say what is wrong, the AI finds the file, fixes it, and hands it to a developer to approve

■ **LLM** = Language Model (like ChatGPT) — reads and writes text, including code

■ **Agent** = A program that uses an LLM in a loop, deciding its own steps

What I learned

Start absurdly small

We didn't build an AI that writes apps. We picked the smallest useful thing: fixing typos. That's how we shipped in 6 hours.

Guardrails, not access

The agent creates a pull request, never deploys directly. A human developer always reviews. Trust comes from the safety net.

100 lines to prototype, 5 hours to integrate

smolagents + LiteLLM got us an agent fast. The real work was wiring Git, the API, and debugging the plumbing.

Know your limits

Reading all files works for a small repo. For large codebases, you need embeddings and search (RAG). Scope your MVP honestly.

Now: live demo →

Future work

Before the agent touches any code — know what you are dealing with

JEV Classifier

A triage step **before** the agent runs: classify the incoming request as a small fix or a larger feature

Small fix

Typo, broken link, wrong label → agent runs automatically

Strong feature

New page, logic change, complex refactor → routed to a developer

Why it matters

The agent is great at small, scoped fixes — but risky on big changes. A classifier as a gatekeeper means we only send the right tasks to the right track.

Less wasted compute, fewer bad PRs, happier developers.
